Acknowledgment is due W. T. Schwenk and Sons, Edwards, Illinois, and the Shawnee High School, Union county, Illinois, for providing land for two of the tests; to W. C. Jacob and Robert Seif for processing the data; to H. L. Portz, D. R. Browning, and E. Arnzin for conducting the Wolf Lake tests; and to L. H. Lindblom and H. M. Hoyes for aid in field and laboratory. Tests in DeKalb, Champaign, and Fayette counties were located on University of Illinois forms managed by R. E. Bell, C. H. Farnham, and P. E. Johnson.

PERFORMANCE OF EXPERIMENTAL CORN HYBRIDS IN ILLINOIS, 1957

By R. W. Jugenheimer, K. E. Williams, and A. J. Crowley, Jr. 1

LLINOIS, the center of the corn belt, leads the surrounding states in corn yields per acre. During the ten years 1947-1956, Illinois farmers averaged 55 bushels per acre. These yields have resulted from the use of superior-performing hybrids and modern production practices by efficient seedsmen and farmers. The high yields have brought total production to the point where corn breeders now have the opportunity to reduce the emphasis on yield and to concentrate on developing inbred lines and hybrids that have improved standability, chemical composition, quality, machine harvestability, ear droppage, and resistance to such hazards as insects, diseases, cold, and drouth.

The development and evaluation of superior-performing hybrids is a gradual but continuing procedure. For example, Ill. 960 and Iowa 939 were widely grown in the early days of hybrid corn. These hybrid combinations were completely replaced by such hybrids as Ill. 21 and U.S. 13. These latter hybrids are now rapidly being supplanted by such hybrids as Ill. 1270, Ill. 1570, AES 702, and AES 805. In turn, some of the new experimental Illinois hybrids appear to be superior to these popular combinations.

Illinois hybrids continue to compare favorably with closed-pedigreed hybrids. This is to be expected, of course, since many hybrid seed producers have put out Illinois hybrids under different names or have modified them only slightly by substituting one or two inbred lines. Although many seedsmen use private codes on Illinois hybrids in order to conceal the pedigree of their hybrids, in 1957 some twenty hybrids were grown and certified under their original Illinois designations. Much of this certified seed was grown for sale at wholesale or in interstate commerce; a federal regulation prohibits the assignment of synonyms to corn hybrids used in interstate commerce.

This report summarizes the results of advanced tests of experimental corn hybrids conducted in 1957 by this Station. Data from many preliminary tests involving specialized phases of the corn-research program are not included in this bulletin.

¹ R. W. Jugenheimer, Professor of Plant Genetics; K. E. Williams, Fieldman in Agronomy; and A. J. Crowley, Jr., Research Assistant.

Trials were made at five locations: in DeKalb county in northern Illinois, in Peoria county in north-central Illinois, in Champaign county in central Illinois, in Fayette county in south-central Illinois, and in Union county in southern Illinois. These five locations are representative of the soil, rainfall, and length of growing season in their respective areas.

Hybrids were compared for grain yield, maturity, shelling percentage, standability, ear height and resistance to smut. Only hybrids of similar maturity were tested on the same field. A familiar hybrid whose maturity was considered the standard for the group is named in each table heading.

Since most of the hybrids whose performance is recorded here are not yet in commercial use, the information about them is of most value to producers of hybrid seed. The 1957 performance of hybrids available to farmers in commercial quantities is reported in Bulletin 622 of this Station.

MATERIAL TESTED

Double crosses for consideration of seedsmen. Three hundred and fifty-five different double-cross hybrids were grown at the five locations. Most of the 300 selected Illinois hybrids were developed by the senior author. The seed was produced by controlled hand-pollination.

The double-cross hybrids whose performance is shown in this report and the tables in which each appears are shown in Table 22, which also contains the pedigrees of the hybrids tested. In the pedigrees, the order of the single crosses and of the lines in the single crosses has no significance; it does not indicate which should be used as seed or pollen parent.

Illinois yellow hybrids are numbered consecutively below 2000 and above 3000. White hybrids are numbered in the 2000 series; these white hybrids are usually followed by the letter W. Hybrids that have performed well after regional testing in several corn-belt states have been designated AES (Agricultural Experiment Station) hybrids. Hybrids in the 600 series are similar to Illinois 1277 in maturity; those in the 700 series correspond in maturity to Illinois 21; those in the 800 series correspond to Illinois 1570; and those in the 900 series to Illinois 1851.

The letter A or B following an Illinois hybrid number indicates that the combination of inbred lines making up the hybrid has been rearranged or permuted. For example, if the original pedigree of an Illinois hybrid was (1×2) (3×4) , the letter A following the num-

ber means that the hybrid was put together (1×3) (2×4) , the letter B, (1×4) (2×3) . A difference in reciprocals is not recognized in this method. When a short dash (-) followed by a number occurs as part of an Illinois hybrid number, it means that a tested related line has been substituted for one of the inbred lines included in the original hybrid.

The University of Illinois does not produce hybrid seed corn in commercial quantities. Hybrids that include new inbred lines may be produced under the "delayed-release" program adopted by the states in the corn belt. Multiplication of a new line is handled by the Station, and the production of single crosses in quantity is handled by the Illinois Seed Producers Association, Champaign, Illinois. If a new Illinois experimental hybrid gives satisfactory performance, the parental lines eventually are released for use by seedsmen.

In order to make the results of corn research more quickly available to the public, the University of Illinois has adopted a slight modification of the "delayed-release" policy as it pertains to Illinois-developed inbred lines. Inbred lines of corn developed by the University of Illinois may be released to the public when they have demonstrated superior combining ability for yield, standability, disease resistance, insect resistance, chemical composition, male sterility, or other characters. Such Illinois lines may form a part of a new hybrid or be used in other ways by corn breeders. Inbred lines of corn developed by others will not be released without their approval.

Hand-pollinated inbred seed of released lines will be available for a fee in packets containing 25 to 100 kernels. Releases will be announced annually on or about April 1. Inquiries may be addressed to the senior author, Agronomy Department, University of Illinois, Urbana, Illinois.

Hybrids for prediction studies. Five sets of single crosses, two sets of three-way crosses, one set of top crosses, and five sets of inbred lines differing in maturity were tested in 1957. The three-way crosses and top crosses (Tables 3, 12, and 20) are a part of the "uniform" tests conducted cooperatively by cornbelt states and the U. S. Department of Agriculture. Seed of the unreleased inbred lines involved in these crosses was contributed by the state or by the federal corn breeder who developed them. Single crosses and inbred lines whose performance is reported in Tables 4, 5, 7, 8, 13, 14, 15, 16, 18, 19, and 21 were developed by the Illinois Station and tested only in Illinois.

The following individuals are responsible at the present time for collecting seed of inbred lines, making the crosses, and distributing

crossed seed of the entries in the cooperative uniform tests: E. C. Rossman (Michigan), D. Linden (Minnesota), N. P. Neal (Wisconsin). and G. H. Stringfield (Ohio) — Table 3; J. H. Lonnquist (Nebraska), R. W. Jugenheimer (Illinois), and G. F. Sprague (Iowa) — Table 12; and W. R. Findley (Kansas), F. A. Loeffel (Kentucky), and M. S. Zuber (Missouri) — Table 20.

Performance of single-cross, three-way-cross, and top-cross hybrids is of interest to corn breeders, producers of hybrid seed corn, and farmers. Characteristics of single crosses such as yield, standability, and size, shape, and quality of seed definitely affect the practical production of hybrid seed corn. Some farmers are interested in growing single-cross and three-way-cross hybrids commercially because of their attractive appearance and extreme uniformity. Use of single-cross and three-way-cross data for the prediction of desirable double-cross combinations creates additional interest in the performance of single crosses and three-way crosses.

Prediction studies are an extremely valuable part of a research program. Methods are available to predict the performance of the better hybrid combinations without making and testing large numbers of undesirable crosses. For example, 1,225 single crosses and 690,900 double crosses are possible with 50 inbred lines. However, by using single-cross performance data, the corn breeder can predict which of the many possible double-cross combinations are likely to be most desirable. The following six single crosses can be made with four inbred lines: $A \times B$, $A \times C$, $A \times D$, $B \times C$, $B \times D$, and $C \times D$. The average performance of the four non-parental single crosses gives the predicted performance of a specific double-cross hybrid. For instance, the average yields of the four single crosses A X C, A X D, B X C, and $B \times D$ give the predicted yield of double cross $(A \times B)$ $(C \times D)$. The procedure in predicting acre yields and percentage of erect plants from single-cross data is shown on page 6 of Illinois Agricultural Experiment Station Bulletin 597.

Similar predictions can be made for other characteristics. Predicted hybrid combinations, however, should always be thoroughly tested under field conditions before being put into commercial production.

Three-way crosses also provide useful predictions of the performance of double-cross hybrids. A large number of inbred lines can be compared, and the method is especially valuable where a desirable seed-parent single cross is available for use as a tester. Three-way crosses provide information on specific hybrids and may often eliminate the

time and expense required for testing inbred lines in top crosses and single crosses. The procedure in predicting acre yields and percentage of erect plants from three-way-cross data is also shown on page 6 of Bulletin 597.

Top crosses are simple to produce and often are useful in early stages of a breeding program. For example, a single cross from the corn belt of the United States might contribute genes for high yield and standability, and an open-pollinated variety from Europe might contribute adaptation to local European conditions. Such top crosses might thus combine the desirable traits of the American single cross and the European open-pollinated variety. Most top crosses, however, are temporary expedients, which usually are eventually replaced by double crosses. Top crosses are useful also for evaluating the performance of inbred lines. They also provide a means of selecting promising open-pollinated varieties for use as source material for the development of inbred lines.

MEASURING PERFORMANCE

General information concerning the tests is given in Table 1.

Field plot design. Semi-balanced lattice designs were used to obtain the data reported in Tables 3, 4, 7, 12, 13, and 14. The data in Tables 5, 8, 15, 16, 19, and 20 were obtained in randomized blocks.

Table 1.—GENERAL INFORMATION: Tests of Illinois
Experimental Corn Hybrids, 1957

Fayette	South-Central	18-19	3	Tune 26	Nov. 21
Union	Southern	20	4	May 2	Oct. 18

^{*}The fields are located near the following cities and towns: in DeKalb county near DeKalb, in Peoria county near Peoria, in Champaign county near Urbana, in Fayette county near Brownstown, and in Union county near Wolf Lake.

8

Rectangular and simple lattice designs were used for the data reported in Tables 2, 6, 9, 10, 11, 17, and 18. Because of time limitations, the data from the rectangular and simple lattice designs were analyzed by the procedure normally used for randomized block designs.

Method of planting. All plots in these tests were planted, thinned, and harvested by hand in well-fertilized fields prepared in the usual way for corn. Individual plots were 2×5 hills in area. Six kernels were planted in hills spaced 40 inches apart. Hills were thinned to 4 plants at DeKalb, Peoria, Champaign, and Wolf Lake, and to 3 plants at Brownstown.

Acre grain yields. Acre yields are reported as shelled grain containing 15.5 percent moisture, the maximum allowable for No. 2 corn. Data from all plots are included in the report on yield. The only correction for imperfect stands was the following adjustment for missing hills:

Ear weight in field
$$\times \left[1 + \left(\frac{\text{missing hills}}{\text{hills present}} \times .7\right)\right] = \text{adjusted ear weight}$$

This adjustment adds 0.7 percent of the average hill yield for each missing hill, and assumes that 0.3 percent is made up by the increased yield of surrounding hills.

Shelling percentage and moisture in grain. All ears from one replication of each entry of the double crosses, three-way crosses, and inbred lines were shelled immediately after harvest. Two replications of the single crosses were shelled. The percentage of moisture in the shelled grain was determined with a Steinlite moisture meter.

Stand. Counts of the number of missing hills and number of missing plots were made in late summer in each plot. The data are reported as percentage of a perfect stand. Yields were corrected for missing hills.

Ear height. Representative plants in each plot were measured to determine the distance in inches from the soil to the ear-bearing node.

Erect plants. Percentage of erect plants in each plot of each entry was determined by actual counts at the time of harvest. Stalks broken above the ear were not considered lodged. Stalks leaning less than 45 degrees were considered as erect.

Smutted plants. The number of smutted plants was recorded on all plots in late summer. These data are reported in the tables as percent of smutted plants.

RESULTS OF THE TESTS

Data obtained from the tests are summarized in Tables 2 to 21. Long-time averages are more reliable indexes of the performance of hybrids than a single year's result. The parts of the tables summarizing the results of two or three years therefore deserve the most weight when the results are studied.

Relative performance cannot be determined with absolute accuracy by any method of testing. Small differences between entries are seldom of any significance. In fact, small differences are to be expected among plots planted even with the same lot of seed. Variations in growing conditions such as soil fertility are reduced but not completely eliminated by replicating the same entry several times in the same test. Unavoidable variation may be determined by a mathematical procedure known as analysis of variance. From this procedure figures may be obtained that represent the range which differences between two entries must exceed before those entries can be considered significantly different. The method used to determine this range is called the "Multiple Range Test." This method considers the number of entries that fall within the range as well as the variability of the test. Data shown in bold-face were not statistically different from the best performance for that characteristic.

Double-cross hybrids that were high yielding and had excellent standability are indicated by heavy type in Table 22.

The following single crosses, three-way crosses, top crosses, and inbred lines were outstanding in performance in 1957:
